Nunavut Nukkiksautiit Corporation (NNC) is a 100% Inuit-owned subsidiary of Qikiqtaaluk Corporation (QC). That means NNC works for the benefit of Qikiqtani Inuit.

NNC was created in 2017 in response to the desire of Qikiqtani communities to explore renewable energy. We develop Inuit- and community-led projects that advance energy sovereignty in Nunavut.

IQALUIT NUKKIKSAUTIIT PROJECT

The Iqaluit Nukkiksautiit Project is a renewable power project that will transform Iqaluit's energy landscape.

The Project is proposing a water power plant along the Kuugaluk River, about 60 km northeast of Iqaluit.

The Project has the potential to become Iqaluit's main electricity source, replacing diesel-generated electricity with clean, renewable power. It also has the potential to be made bigger to supply electricity for heating homes and businesses in Iqaluit, or for producing electricity for industrial users, such as future mines nearby.

This booklet provides an update on the 2024 field program findings, the resulting impacts to the Project concept, and outlines the planned activities over the next year. It also presents additional project options for your consideration and input.

NNC follows a “Phase Gate” approach to delivering projects. Engagements with Rightsholders, the public, stakeholders, and partners are part of every Phase, to ensure we are taking direction from Rightsholders in project decision-making, and that all parties have input. Between each Phase there is a Decision Gate which requires approval to move on to the next Phase from engagement participants and Inuit leadership.

Phase 1:
Identify Opportunity
NNC identified the value to Iqalungmiut in exploring clean power solutions to meet Iqaluit's needs. NNC completed a Technical and Economic Feasibility Review, a Tusaqtavut Study on Inuit land-use, and a desktop Environmental Survey.

Decision Gate 1:
Should clean power be further explored for Iqaluit?
Inuit leadership from Qikiqtaaluk Corporation and Qikiqtani Inuit Association supported doing more studies to find the best path forward.

Phase 2 :
Feasibility
17 different power system options were identified at sites near Iqaluit, including different types of water power, wind power, a combination of water and wind, and continuing with diesel.

The site investigations found more gravel than we originally anticipated, and the depth to bedrock is currently unknown.

This means the reservoir cannot be as large as we first thought.

To meet Iqaluit's electricity demand, it is possible (but not yet determined) that a second supporting reservoir upstream from the main reservoir may be needed. Or, supplemental wind power could be added to meet the Project's electricity generation target.

As we advance with Phase 3 of the Project, we will continue to apply the “three-legged stool” approach.

Equal importance will be placed on the economic, environmental and social values of the Project. There are unknowns and uncertainties about each of these ‘legs’ that need to be determined and will continue to shape the Project scope.

As we gather information on these unknowns our engineers will be able to **develop a preliminary design.**

The design will be an iterative process based on continued information that is gathered about each of the Project values.

There are some immediate unknowns that NNC will begin investigating. We will report back to the community on the investigation findings.

Examples of unknowns that we are investigating include:

- Are there archaeological sites along the proposed access road and nearby the Project site?
- What are the above and below ground conditions at the Project site?
- Will wildlife be impacted, including fish and fish habitat, birds, and land animals?
- What is the extent of trail systems near the site?
- How will the Project connect with Qulliq Energy Corporation's (QEC) existing electricity grid?
- Can a power purchase agreement, or another commercial agreement, with QEC be achieved to make the Project economically feasible?

The current Project concept assumes the Project will produce clean power to meet Iqaluit's current and future electricity demand. We consider this the **base scenario**.

In addition to the base scenario, NNC is considering investigating two additional options:

- **Additional Option 1:** produce more clean power for Iqaluit's heating needs. This would require homes and buildings to switch to electric heating methods.

- **Additional Option 2:** produce more clean power for off-site industrial electricity demand, such as a future mine near Iqaluit.

The Project may be able to support either Additional Option 1 or Additional Option 2, but not both additional options.

Do you want NNC to explore Additional Option 1?

NNC's exploration of Additional Option 1 would include answering questions such as:

- How would homes and buildings be converted to electric heat?
- Who would pay for this?
- Would electric heat be less expensive?
- How would this affect the Project scope and cost?
- Would this impact the environment and the community differently from the base case?

Do you want NNC to explore Additional Option 2?

NNC's exploration of Additional Option 2 would include answering questions such as:

- What future industrial demand can we expect?
- How would this affect the Project scope and cost?
- Would this impact the environment and the community differently from the base case?

When will the water power plant be operational?

The earliest we could expect the plant to be operational is 2033. There are still many studies needed, regulatory processes to move through, and financing is yet to be secured. This is a very typical timeline for a new water power project in Canada.
